

Temporal Dynamics of a Half-Billion-Edge Legal Citation Network: Structural Resilience Across Reform and War in Ukrainian Courts

Volodymyr Ovcharov
LEX AI LLC, Kyiv, Ukraine
vladimir@legal.org.ua

Abstract

Static snapshots of legal citation networks conceal the dynamics that reveal how legal systems respond to reform, crisis, and conflict. We present the first temporal analysis of a legal citation network at the hundred-million-decision scale: 386 million deduplicated citation events from 101 million Ukrainian court decisions (2007–2026), decomposed into five event-aligned periods spanning pre-Maidan baseline, post-revolution reforms, judicial modernization, pre-invasion stability, and full-scale war.

Using sparse matrix co-citation ($M^\top M$ on $10^7 \times 5,000$ matrices, computed in seconds per period) with year-normalized weights and a fixed node set across all periods, we construct period-specific co-citation networks totaling 3.9 million edges across five temporal windows. Leiden community detection on a stable set of 5,000 most-cited legislation articles reveals consistently high modularity ($Q = 0.60$ – 0.63 across all periods, $z > 600$), with 8–14 well-separated communities corresponding to legal domains.

Normalized mutual information between consecutive periods quantifies stability: NMI ranges from 0.77 (P3→P4, the post-reform consolidation period) to 0.84 (P1→P2, pre-reform baseline), with the 2022 invasion transition at NMI = 0.81 (P4→P5). All transitions maintain NMI > 0.76 (where NMI = 0 indicates random reassignment and NMI = 1 indicates identical partitions), confirming that community structure is robust across all major events. War introduces dramatic individual-law changes (martial law citations growing 4,000×) but preserves the overall community architecture (NMI = 0.81). Citation entropy analysis with formal break detection ($\pm 2\sigma$ threshold) confirms system-level resilience: no individual year produces a statistically significant distributional anomaly.

The co-citation graph, community assignments, and analysis code are released as open data.

Keywords: temporal networks, legal citation graph, community evolution, structural resilience, Ukrainian courts, judicial reform, war impact, EDRSR

1 Introduction

Legal citation networks encode the operational structure of a legal system: which norms courts actually apply, how frequently, and in what combinations. Prior work has constructed such networks for the US Supreme Court [4], Dutch case law [14], Danish courts [7], and French legal codes [6]. These studies, however, treat citation networks as static objects – aggregated across decades, analyzed at a single time point. The temporal dimension – how citation patterns evolve in response to legislative reform, societal crisis, and institutional change – remains largely unexplored at scale.

The companion paper [9] constructed the first large-scale legal citation graph from the complete Ukrainian court record: 502 million citation edges from 101 million decisions, with community structure that recovers legal domain boundaries. That analysis was static: all years collapsed into a single graph. This paper develops the temporal dimension.

We decompose the citation record into five event-aligned periods spanning two decades of Ukrainian legal history: the pre-Maidan baseline (2007–2013), post-revolution reforms (2014–2016), judicial modernization (2017–2019), pre-invasion stability (2020–2021), and the full-scale Russian invasion (2022–2026). For each period, we compute co-citation networks via sparse matrix multiplication and track community evolution across periods.

Four research questions guide the analysis:

- RQ1:** Does the co-citation community structure change in response to legislative reform, and if so, how sharply?
- RQ2:** How fast do courts adopt new legislation, and does adoption speed vary by region?
- RQ3:** Does the co-citation community structure evolve gradually or through discrete jumps?
- RQ4:** What structural signature does the 2022 full-scale invasion leave on the citation network?

Our principal finding is that community structure is consistently stable across all transitions ($Q \approx 0.62$, $\text{NMI} > 0.76$, where $\text{NMI} = 0$ would indicate random reassignment), with the post-reform consolidation period associated with the largest restructuring ($\text{NMI} = 0.77$) and the 2022 invasion producing less disruption ($\text{NMI} = 0.81$) despite introducing entirely new legislative clusters. Yearly modularity analysis (2010–2025) shows gradual evolution rather than sharp breaks, with Q fluctuating between 0.51 and 0.72. This suggests that the legal system’s domain structure is resilient to both institutional reform and armed conflict – a finding with implications for legal system design and ontology-based legal informatics.

2 Related Work

2.1 Temporal Network Analysis

Holme and Saramäki [5] provide a comprehensive review of temporal networks, distinguishing between contact sequences (edges with timestamps) and interval graphs (edges active during windows). Our approach falls into the latter category: we construct period-specific co-citation networks and analyze their evolution. Key metrics from the temporal networks literature that we apply include normalized mutual information for comparing community partitions across time [3] and modularity for measuring community separability [8].

2.2 Legal Network Evolution

Coupette et al. [2] introduced a framework for measuring legal evolution through network analysis, applying it to US federal statutes and German regulations ($\sim 10^4$ nodes). Their work tracks structural properties (density, clustering, degree distribution) over time but does not analyze co-citation community evolution. Bommarito and Katz [1] studied the US Code as a citation network, identifying hierarchical structure and power-law degree distributions. Neither work operates at the scale of 10^8 decisions or analyzes the temporal dynamics of co-citation communities.

2.3 Innovation Diffusion in Legal Systems

The adoption of new legislation by courts can be modeled as a diffusion process [12]: initially slow adoption by early-adopter courts, followed by rapid spread as the new norm becomes standard

Table 1: Period definitions and dataset statistics.

Period	Years	Decisions	Citations	Context
1	2007–2013	5,196,182	56,708,529	Pre-Maidan baseline
2	2014–2016	9,102,868	102,828,193	Revolution, early reforms
3	2017–2019	6,134,398	58,308,820	Judicial reform, new codes
4	2020–2021	3,633,714	35,428,099	Pre-invasion (COVID)
5	2022–2026	11,415,011	133,369,281	Full-scale invasion

practice, and eventual saturation. We operationalize this through citation time series of new legislation articles and fit logistic adoption curves to measure judicial system responsiveness. To our knowledge, no prior work has measured legislative adoption curves empirically from court citation data at national scale.

3 Data and Methods

3.1 Dataset

The Unified State Register of Court Decisions (EDRSR) contains 101.1 million decision records (2005–2026), of which 100.7 million include full text totaling 1.1 TB. Citation extraction via the regex pipeline described in the companion paper [9] yields 502 million citation edges linking decisions to legislation articles across six citation types: codex articles (79%), case references (13%), law articles (6%), constitutional provisions, supreme court rulings, and laws by number.

After deduplication to unique (decision, law, article) tuples, the dataset comprises 386.6 million citation events spanning 35.5 million unique decisions and approximately 500,000 unique legislation article identifiers.

3.2 Temporal Co-Citation via Sparse Matrix Multiplication

We select a fixed set of $k = 5,000$ legislation articles with the highest citation count across the entire dataset (aggregate over all periods). This fixed set ensures that temporal comparisons are made on identical node sets, avoiding artifacts from period-specific article selection.

For each period t , we construct a binary sparse matrix $M^{(t)} \in \{0, 1\}^{n_t \times k}$, where n_t is the number of decisions and $k = 5,000$ is the fixed article set. The co-citation matrix is computed as $C^{(t)} = (M^{(t)})^\top M^{(t)}$, where entry $C_{ab}^{(t)}$ gives the number of decisions in period t that cite both articles a and b . To account for unequal period lengths (2–7 years), we normalize: $\hat{C}_{ab}^{(t)} = C_{ab}^{(t)} / L_t$, where L_t is the period length in years.

This formulation replaces the $O(n^2)$ SQL self-join with a sparse matrix-matrix product computed via BLAS in seconds per period. The upper triangle of $\hat{C}^{(t)}$ with entries ≥ 5 (co-citations per year) defines the period’s co-citation network. Articles with zero edges (not co-cited with any other article above threshold) are excluded from community detection, yielding 3,887–4,604 active nodes per period (Table 2).

3.3 Community Detection and Evolution

We apply the Leiden algorithm [13] to each period’s co-citation network with edge weights (30 independent runs with 5 iterations each; objective: modularity maximization; resolution parameter

Table 2: Temporal co-citation network statistics (fixed node set, year-normalized weights, Leiden algorithm, 30 iterations). All z -scores indicate modularity far exceeding random expectation.

Period	Nodes	Edges	Density	$Q \pm \sigma$	z	k
1	3,887	457,634	0.059	0.627 ± 0.000	600	14
2	4,544	855,077	0.078	0.633 ± 0.000	828	11
3	4,584	866,769	0.078	0.617 ± 0.000	812	8
4	4,604	780,340	0.072	0.622 ± 0.000	777	8
5	4,604	930,961	0.085	0.607 ± 0.000	828	9

$\gamma = 1.0$). The consensus partition is determined by majority vote across the 30 runs; modularity Q is reported as mean $\pm$ standard deviation. Community evolution is tracked via:

- Normalized Mutual Information (NMI) between consecutive periods on shared active nodes, with bootstrapped confidence intervals (50 subsamples of $n = 1,000$);
- Adjusted Rand Index (ARI) as a chance-corrected agreement measure;
- Modularity Q significance assessed via analytical z -score: $z = Q \cdot \sqrt{2|E|}$, where $|E|$ is the edge count.

Bridge articles are identified by betweenness centrality on the top-1,000 nodes by degree; bridge stability is measured by Jaccard overlap of the top-20 bridge articles between consecutive periods.

3.4 Citation Entropy and Structural Break Detection

Shannon entropy of the citation distribution at year t :

$$H(t) = - \sum_a p_a(t) \log p_a(t), \quad p_a(t) = \frac{c_a(t)}{\sum_{a'} c_{a'}(t)}$$

where $c_a(t)$ is the total citations to article a in year t .

4 Results

4.1 Decision Volume and Citation Dynamics (RQ1)

Figure 1 shows the decision volume by jurisdiction type across 2010–2026. Civil and administrative cases dominate, with a visible dip across all categories in 2022 (invasion year) followed by recovery. Criminal cases show steady growth from 2013 onward, reflecting expanded jurisdiction of criminal procedure courts.

4.2 Community Structure Stability (RQ1, RQ3)

With year-normalized weights and a fixed node set, modularity remains consistently high across all periods ($Q = 0.61$ – 0.63 , Table 2 and Figure 3), indicating that legal domain structure is a persistent feature of judicial citation practice rather than an artifact of any single reform. Yearly modularity analysis (2010–2025, Figure 2) confirms gradual evolution: Q fluctuates between 0.51 and 0.72 (mean = 0.62) without a sharp inflection point at any single year, suggesting continuous adaptation rather than abrupt reorganization.

Figure 4 shows the community evolution across all five periods. The dominant communities correspond to: civil procedure (CPC), criminal procedure and criminal code (KPC/CC), administrative litigation (AdminC), civil substantive law (CivC), commercial procedure (ComPC), and misdemeanor proceedings (KUpAP).

Figure 1: Court decisions per year by jurisdiction type (2010–2026). Dashed lines mark the 2017 judicial reform and 2022 invasion.

Table 3: Community stability between consecutive periods (fixed node set, Leiden, bootstrapped NMI with $n = 1,000$ subsample $\times$ 50 iterations).

Transition	Shared	NMI	Boot $\mu \pm \sigma$	ARI
P1 $\rightarrow$ P2	3,887	0.838	0.844 ± 0.015	0.852
P2 $\rightarrow$ P3	4,544	0.819	0.826 ± 0.013	0.794
P3 $\rightarrow$ P4	4,584	0.765	0.771 ± 0.016	0.734
P4 $\rightarrow$ P5	4,604	0.814	0.821 ± 0.012	0.837

4.3 Community Evolution Stability (RQ3)

Figure 5 shows the bootstrapped NMI between consecutive periods with 95% confidence intervals. The P3 $\rightarrow$ P4 transition (2017 reform consolidation) shows the lowest NMI (0.765 ± 0.016), confirming it as the period of greatest community restructuring. Critically, all transitions maintain NMI > 0.76 , indicating that the majority of community assignments persist across all major events.

4.4 War Impact on Citation Structure (RQ4)

The 2022 full-scale Russian invasion produced the most dramatic individual-law citation changes in the dataset. Citations to the martial law regime act (“On the Legal Regime of Martial Law”) grew from 3 in 2021 to 12,136 in 2022 – a 4,000 $\times$ increase in a single year. Mobilization legislation grew from 1,029 to 32,209 citations by 2025. An entirely new legislative cluster emerged: wartime labor relations ($0 \rightarrow 5,752$ citations).

Despite this dramatic surface change, the community structure NMI between P4 and P5 is 0.81 (Table 3) – higher than the P3 $\rightarrow$ P4 transition (0.77) that coincides with the judicial reform consolidation period. The war introduced new nodes into existing communities rather than restruc-

Figure 2: Yearly modularity Q (2010–2025) on the fixed 5,000-node co-citation graph. No sharp inflection point is visible; Q fluctuates around a stable mean of 0.62.

Table 4: Top bridge article (highest betweenness centrality) and bridge stability per period.

Period	Top bridge	Betweenness	Jaccard _{$t \rightarrow t+1$}
1	Commercial Procedure Code art. 1117	0.125	0.03
2	Civil Procedure Code art. 215	0.323	0.21
3	Civil Procedure Code art. 354	0.309	0.21
4	Supreme Court (case law)	0.675	0.54
5	Supreme Court (case law)	0.752	—

turing community boundaries. Modularity remained stable ($Q = 0.62 \rightarrow 0.61$), and community count shifted from 8 to 9 as wartime legislation formed a small additional cluster absorbed into the administrative law domain.

Figure 6 shows the adoption curves for war-related legislation on a logarithmic scale. Figure 7 visualizes the network community structure before and after the invasion. Citation entropy (Figure 8) fluctuates across years but formal break detection (linear detrending with $\pm 2\sigma$ threshold) identifies no statistically significant anomalies – the variation is within normal inter-annual bounds. This complements the NMI finding: the legal citation system absorbs both reform and war without dramatic distributional shifts.

4.5 Bridge Articles and Betweenness Stability

Betweenness centrality identifies articles that serve as structural bridges between legal domain communities. Table 4 shows the evolution of the top bridge article across periods.

The bridge structure undergoes a qualitative shift: in P1–P3, procedural articles serve as bridges (specific code provisions connecting adjacent domains). After the 2017 reform, the Supreme Court’s case law references become the dominant bridge (betweenness $0.68 \rightarrow 0.75$), reflecting its role as the sole appellate instance connecting all branches of justice. Bridge stability (Jaccard of top-20 bridge articles between consecutive periods) increases monotonically: $0.03 \rightarrow 0.21 \rightarrow 0.21 \rightarrow 0.54$,

Figure 3: Period-level summary: modularity, community count, and edge density remain in stable ranges across all five periods, confirming structural resilience.

Table 5: Logistic adoption curve parameters for wartime legislation. R^2 indicates goodness of fit.

Law	t_{50}	Rate r	R^2	Interpretation
Martial law regime	2021.8	6.2	0.80	Instant adoption
Mobilization	2024.1	1.0	0.90	Gradual, still growing
Wartime labor	2023.4	0.4	0.21	Poor fit (non-logistic)

indicating that the post-reform bridge structure is converging to a stable configuration.

4.6 Adoption Curve Modeling (RQ2)

Logistic curves $c(t) = K/(1 + e^{-r(t-t_{50})})$ fitted to war-related legislation citations yield the following adoption parameters:

The martial law regime act was adopted by courts within weeks of the invasion (effectively $t_{50} < \text{invasion date}$), consistent with the law having existed since 2015 – courts were prepared to apply it when martial law was declared. Mobilization legislation shows a slower adoption curve ($r = 1.0$) reaching half-saturation only in 2024, reflecting the gradual expansion of mobilization-related litigation as the war continued.

4.7 Regional Adoption Speed (RQ2)

Regional analysis of martial law citation adoption reveals significant geographic variation (Figure 9). After normalizing by court count per region, Kyiv City (62.7 citations/court in 2022) and

Community evolution across five periods

Figure 4: Community evolution across five periods (alluvial diagram). Flow width indicates the number of shared nodes between community assignments in consecutive periods.

Dnipropetrovsk Oblast (43.2/court) lead adoption, while frontline regions (Zaporizhzhia, Kharkiv) show elevated per-court intensity consistent with the geographic distribution of conflict-related proceedings.

4.8 Alignment with Formal Legal Domains

Comparing co-citation communities with the formal jurisdiction classification (*justice_kind*: civil, criminal, commercial, administrative, misdemeanor) reveals increasing alignment over time. NMI between Leiden communities and formal domains rises from 0.69 (P2, post-revolution turbulence) to 0.85 (P5, wartime). The wartime period shows the highest formal-practice alignment, indicating that courts under wartime conditions cite more strictly within their formal jurisdictional boundaries – consistent with either reduced case complexity or institutional pressure for faster resolution.

5 Discussion

Citation networks as a judicial observatory. The temporal co-citation analysis demonstrates that legal citation networks function as a real-time observatory for judicial system behavior. Legislative reforms, political crises, and armed conflict all leave measurable structural signatures in the citation graph – without requiring any natural language processing or content analysis. The purely structural signal (which laws are cited together, how often) captures systemic changes that would be difficult to detect from individual case readings.

Figure 5: Bootstrapped NMI between consecutive periods (error bars: $\pm 2\sigma$). All values exceed 0.76, indicating high structural stability. The P3→P4 transition shows the largest community shift.

Reform vs. war: relative disruption. The 2017 judicial reform period is associated with the lowest NMI between consecutive periods (0.77), while the 2022 invasion transition shows higher stability ($\text{NMI} = 0.81$). One plausible explanation is architectural: procedural codes define *how* courts process cases, affecting every decision regardless of subject matter, while war-related legislation is substantive and applies to specific case categories. However, alternative explanations must be acknowledged: the 2017 reform introduced new article identifiers (splitting one procedural code into four domain-specific codes), which could mechanically redistribute nodes across communities. Similarly, court specialization after 2017 (dedicated commercial and administrative courts) may reduce cross-domain citations through institutional routing rather than changed citation practice.

Connection to ontology evolution. The companion paper [9] derived a legal ontology from aggregate co-citation clustering. The temporal stability results here ($\text{NMI} > 0.76$ across all transitions) provide empirical justification for using such an ontology as a stable domain layer in LLM-assisted legal systems [10, 11]: the domain structure is persistent enough to serve as a reliable knowledge scaffold, while the temporal dynamics indicate when ontology updates are needed.

Limitations. Four limitations constrain the analysis. First, coverage gaps in 2008–2009 (data loading anomalies) reduce reliability for Period 1; however, recomputing P1 using only 2010–2013 yields $Q = 0.60$ (vs. 0.63 with all years), confirming the baseline is robust. Second, the top-5,000 article selection from the aggregate graph creates survivorship bias toward older, well-established articles; legislation important only in recent periods may be underrepresented. Third, OCR artifacts in pre-2010 decisions introduce noise into citation extraction for the earliest years. Fourth, unequal period durations (2–7 years) mean later periods have more statistical power despite year-normalization of weights. None of these substantially affect the post-2014 periods where our principal findings lie.

Figure 6: War-related legislation citation curves (2014–2026, log scale). Martial law regime citations grow $4,000\times$ in a single year (2021→2022).

Implications. For legal informatics, temporal citation analysis offers a quantitative framework for monitoring judicial system health: sudden entropy spikes signal legislative disruption, declining NMI signals structural reform, and regional adoption speed variation signals implementation heterogeneity. For policy, the adoption curve methodology provides an empirical measure of judicial system responsiveness to legislative intent.

6 Conclusion

We presented the first temporal analysis of a legal citation network at the hundred-million-decision scale. Decomposing 386 million deduplicated citation events across five event-aligned periods (2007–2026) with year-normalized weights and a fixed node set, we find:

1. Co-citation community structure is remarkably stable across all periods ($Q = 0.61\text{--}0.63$, $NMI > 0.76$ between all consecutive periods), with legal domains persisting as a robust organizational feature of judicial citation practice.
2. The 2022 full-scale invasion introduces dramatic individual-law changes (martial law citations $+4,000\times$) but preserves community architecture ($NMI = 0.81$), while the 2017 reform period shows the largest (though moderate) restructuring ($NMI = 0.77$).
3. Sparse matrix co-citation ($M^\top M$) with year normalization computes period networks from 10^8 citations in seconds, making temporal analysis of national-scale legal systems computationally tractable.
4. Regional adoption analysis reveals geographic heterogeneity in wartime legislation citation intensity, with frontline regions showing disproportionate activity.
5. Bridge article analysis reveals a qualitative shift: the Supreme Court’s case law becomes the sole structural bridge connecting all legal domains after the 2017 reform (betweenness

Period 4: 2020–2021

Period 5: 2022–2026

Figure 7: Co-citation network community structure: Period 4 (2020–2021, left) vs. Period 5 (2022–2026, right). Top 200 edges by weight; node color indicates Leiden community assignment.

0.68 $\rightarrow$ 0.75), with bridge stability converging over time (Jaccard 0.03 $\rightarrow$ 0.54).

The co-citation networks, community assignments, and analysis code are released as open data to enable replication and extension to other jurisdictions.
