

Temporal Dynamics of a Legal Citation Network at National Scale: Clarification, Consolidation, and Wartime Reorganization

Volodymyr Ovcharov

vladimir@legal.org.ua

Abstract

We present the first full-scale temporal analysis of a national legal citation network: 345 million citation events from 33 million Ukrainian court decisions (2007–2026), decomposed into five event-aligned periods. Using data-driven co-citation analysis on 18,000–29,500 legislation articles per period (50–102 million edges each), we uncover a three-phase structural dynamic validated by five independent methods.

Phase I – Clarification (2007–2019): community count declines while spectral separability increases 14-fold (Fiedler λ_2 : 0.0027 $\rightarrow$ 0.0002), indicating fewer but sharper legal domains. *Phase II – Consolidation and disruption* (2020–2026): the pre-invasion period achieves near-perfect stability (NMI = 0.96), followed by the 2022 invasion producing the strongest structural shock of any transition (NMI = 0.77, $p < 10^{-4}$ vs. all others), splitting civil procedure and crystallizing a new administrative/misdemeanor domain. *Phase III – Reorganization*: the wartime $k = 5$ partition stabilizes rapidly (within-period NMI = 0.94) and captures citation-practice distinctions invisible to semantic embeddings (co-citation vs. LLM NMI: 0.71 at peak, diverging to 0.43 under war).

Five validations confirm these findings: formal jurisdiction alignment (NMI 0.46–0.71), sub-period stability, bootstrap significance tests, spectral analysis, and LLM embedding comparison. Results are robust to resolution, threshold, and period boundary (± 1 year) variation.

Keywords: temporal networks, legal citation graph, community evolution, spectral analysis, text embeddings, Ukrainian courts, war impact, EDRSR

1 Introduction

Legal citation networks encode the operational structure of a legal system: which norms courts actually apply, how frequently, and in what combinations. Prior work has constructed such networks for the US Supreme Court [4], Dutch case law [12], Danish courts [7], and French legal codes [6]. These studies treat citation networks as static objects. The temporal dimension – how citation patterns evolve in response to reform, crisis, and conflict – remains largely unexplored at scale.

The companion paper [9] constructed the first large-scale legal citation graph from the complete Ukrainian court record: 502 million citation edges from 101 million decisions. That analysis was static. This paper develops the temporal dimension and introduces two methodological advances: (i) data-driven node selection that eliminates the survivorship bias of fixed top- k approaches, and (ii) multi-method validation combining graph-theoretic, statistical, and semantic analyses.

We decompose the citation record into five event-aligned periods spanning two decades of Ukrainian legal history: the pre-Maidan baseline (2007–2013), post-revolution reforms (2014–2016),

Table 1: Period definitions and dataset statistics.

P	Years	Decisions	Citations	Context
1	2007–2013	5,002,786	43,332,281	Pre-Maidan baseline
2	2014–2016	8,445,825	79,035,492	Revolution, early reforms
3	2017–2019	5,725,724	58,594,163	Judicial reform
4	2020–2021	3,350,036	36,534,579	Pre-invasion (COVID)
5	2022–2026	10,553,570	128,017,684	Full-scale invasion

judicial modernization (2017–2019), pre-invasion stability (2020–2021), and the full-scale Russian invasion (2022–2026).

Four research questions guide the analysis:

RQ1: Does co-citation community structure change in response to legislative reform?

RQ2: How fast do courts adopt new legislation, and does speed vary by region?

RQ3: Does community structure evolve through gradual drift or discrete shocks?

RQ4: What structural signature does the 2022 invasion leave on the citation network?

Our principal finding is a three-phase dynamic: *clarification* (fewer but spectrally sharper communities, P1–P3), *consolidation and disruption* (maximum stability then maximum shock, P3–P5), and *reorganization* into a new five-domain structure that stabilizes rapidly. The invasion is the strongest structural shock ($p < 10^{-4}$) – a finding that was masked by fixed-node analyses and is confirmed by five independent validation methods.

2 Related Work

Holme and Saramäki [5] review temporal networks; we adopt the interval-graph approach with period-specific co-citation networks. Coupette et al. [2] track structural properties of US and German legal networks over time ($\sim 10^4$ nodes) but do not analyze co-citation community evolution. Bommarito and Katz [1] study the US Code as a citation network. Neither work operates at the scale of 10^8 decisions or combines community detection with spectral and embedding validation.

Spectral analysis of network evolution follows Newman and Girvan [8] on modularity and Fiedler [3] on algebraic connectivity. Our use of the Fiedler value as a detection-independent separability measure complements partition-based metrics (NMI, ARI).

The adoption of new legislation by courts can be modeled as a diffusion process [10]. To our knowledge, no prior work has measured legislative adoption curves from court citation data at national scale.

3 Data and Methods

3.1 Dataset

The Unified State Register of Court Decisions (EDRSR) contains 101 million decisions (2005–2026). Citation extraction yields 502 million edges; after deduplication within periods, 345.5 million citation events spanning 33.1 million decisions (Table 1).

3.2 Temporal Co-Citation

For each period t , we include all legislation articles cited by at least $\tau \cdot L_t$ decisions ($\tau = 5$, $L_t =$ period years). This data-driven pre-filter is principled: articles below this threshold cannot generate

Table 2: Co-citation network statistics. z -scores from degree-preserving null model ($N_{\text{null}} = 5$). λ_2 : Fiedler value of normalized Laplacian (algebraic connectivity).

P	Articles	Nodes	Edges (M)	ρ	Q	z	k	λ_2
1	29,393	18,263	55.6	0.333	0.027	18.7	8	0.00269
2	29,902	29,476	101.9	0.235	0.415	4,493	6	0.00076
3	29,685	29,377	101.0	0.234	0.311	2,637	4	0.00019
4	18,883	18,477	49.8	0.292	0.059	391	3	0.00946
5	21,147	18,533	49.8	0.290	0.265	1,848	5	0.01116

co-citation weight $\geq \tau$ with any article. Unlike fixed top- k selection, it adapts to each period and avoids survivorship bias (Figure 11).

We construct a sparse binary matrix $M^{(t)} \in \{0, 1\}^{n_t \times k_t}$ and compute the co-citation matrix $C^{(t)} = (M^{(t)})^\top M^{(t)}$, normalized by period length: $\hat{C}_{ab}^{(t)} = C_{ab}^{(t)} / L_t$. The upper triangle with entries $\geq \tau$ defines the co-citation network (Table 2).

3.3 Community Detection

We apply Leiden [11] with 30 consensus runs ($\gamma = 1.0$, modularity maximization). All runs converge to the same partition ($\sigma_Q < 10^{-4}$). Modularity significance is confirmed via degree-preserving null models (all $z > 18$).

Community evolution is tracked via NMI and ARI on shared active nodes (18,094–28,989 per transition), with 1,000-iteration bootstrap confidence intervals.

3.4 Validation Methods

We apply five independent validation approaches:

1. *Formal jurisdiction*: NMI between communities and the five-class *justice_kind* metadata.
2. *Sub-period stability*: split P5 into 2022–2023 and 2024–2026; compare partitions.
3. *Statistical significance*: pairwise bootstrap comparison of NMI across transitions.
4. *Spectral analysis*: Fiedler value λ_2 of the normalized Laplacian as a detection-independent separability measure.
5. *Semantic embeddings*: k -means clustering of multilingual LLM embeddings (intfloat/multilingual-e5-large, 1,024 dims) compared with co-citation communities.

4 Results

4.1 Community Structure Recovers Legal Domains

Leiden community detection recovers recognizable legal domains in every period (Table 3). Four core domains persist: commercial procedure (CPC_{com}), civil substantive (CC), civil procedural (CPC_{civ}), and criminal (CrC/CrPC).

4.2 Phase I: Clarification (RQ1, RQ3)

The effective community count declines from $k_{\text{eff}} = 4$ (P1; raw $k = 8$ includes 4 micro-clusters of 2 nodes) through $k = 4$ (P3) to $k = 3$ (P4), as the commercial appeals sub-community merges with commercial procedure and civil domains consolidate (Table 3, Figure 1).

Table 3: Community domains by period. Only communities with > 100 nodes; P1 has 4 additional micro-communities (2 nodes each).

P	Domain	Nodes	Top legislation
1	Commercial procedure	9,997	CPC _{com} art. 1117, 1119
	Civil procedure + pensions	6,293	CPC _{civ} art. 215, 88
	Commercial appeals	1,015	CPC _{com} art. 107, 112
	Criminal	950	CrC art. 185; CrPC art. 323
3	Commercial procedure	10,015	CPC _{com} art. 1117, 1119
	Civil substantive	9,523	CC art. 1055, 1218
	Civil proc. + obligations	8,631	CC art. 1054; CPC _{civ} art. 141
	Criminal	1,208	CrC art. 185; CrPC art. 177
4	Civil substantive	9,483	CC art. 10561, 1241
	Civil procedure	7,831	CPC _{civ} art. 81, 141
	Criminal	1,163	CrC art. 185; CrPC art. 177
5	Civil substantive	9,473	CC art. 1227, 1221
	Civil proc. (first instance)	3,135	CPC _{civ} art. 141, 81
	Admin + misdemeanor	2,416	CAO art. 130; APC art. 77
	Civil proc. (cassation)	2,240	CPC _{civ} art. 392, 447
	Criminal	1,269	CrC art. 185; CrPC art. 177

Table 4: Community stability. Invasion transition (P4→P5) significantly lower than all others ($p < 10^{-4}$, 1,000-iteration pairwise bootstrap).

Transition	Shared	NMI	95% CI	ARI	p vs P4→P5
P1 → P2	18,094	0.826	[0.804, 0.848]	0.869	$< 10^{-4}$
P2 → P3	28,989	0.863	[0.846, 0.879]	0.874	$< 10^{-4}$
P3 → P4	18,315	0.960	[0.933, 0.984]	0.983	$< 10^{-4}$
P4 → P5	18,338	0.770	[0.748, 0.790]	0.752	–

Crucially, this is not mere coarsening. The Fiedler value λ_2 *decreases* from 0.0027 (P1) to 0.0002 (P3) – a $14\times$ drop (Table 2) – indicating that the remaining communities become progressively *more separable*, not less. At P3, the ratio $\lambda_2/\lambda_3 = 0.02$ indicates a strong spectral gap: the graph has a well-defined bipartition far more pronounced than any subsequent split. This is *clarification*: fewer domains, each spectrally sharper.

Transition stability confirms gradualism: NMI increases monotonically from 0.826 (P1→P2) to 0.960 (P3→P4; Table 4), with the pre-invasion period achieving near-perfect partition preservation.

P1 warrants methodological caution: density $\rho = 0.33$ and modularity barely above null ($Q = 0.027$, $Q_{\text{null}} = 0.026$). The 7-year window inflates edge count despite weight normalization.

4.3 Phase II: Wartime Disruption (RQ4)

The P4→P5 transition yields the lowest NMI of any period pair: 0.770 (95% CI: [0.748, 0.790]; Table 4, Figure 4). Pairwise bootstrap comparison confirms this is significantly lower than every other transition ($p < 10^{-4}$).

Of the 18,338 shared nodes, 5,781 (31.5%) change community. Three flows account for 98% of movement:

- *Civil procedure* → *admin/misdemeanor* (2,293 nodes): CAO, APC, and court fee articles

Figure 1: Community evolution (alluvial diagram, 6,666 core nodes, $\sim 36\%$ of smallest period). Restriction to core nodes biases toward stability; the full analysis (Table 4) uses all shared nodes per transition.

separate into a distinct cluster incorporating wartime administrative law.

- *Civil procedure* $\rightarrow$ *cassation* (2,240 nodes): cassation articles (CPC_{civ} art. 392, 447) separate from first-instance procedure.
- *Criminal intact* (1,141 nodes): the criminal domain moves as a coherent block.

At the individual-law level, martial law citations grew from 3 in 2021 to 12,136 in 2022 ($4,000\times$); mobilization grew to 32,209 by 2025 (Figure 8).

The spectral signature confirms disruption: λ_2 jumps $50\times$ from 0.0002 (P3) to 0.0095 (P4), indicating that the consolidation destroyed spectral separability. P5 shows $\lambda_2 = 0.0112$ – the five new communities exist but remain spectrally soft.

4.4 Phase III: Wartime Reorganization

The reorganized $k = 5$ structure stabilizes rapidly. Sub-period analysis (Table 5) shows identical community count in both halves of P5, with NMI = 0.942 (ARI = 0.980) between 2022–2023 and 2024–2026. The disruption occurs at the invasion boundary (P4 $\rightarrow$ P5a: NMI = 0.777); afterward, the partition persists.

Citation entropy (Figure 7) shows no statistically significant anomaly at any year ($\pm 2\sigma$), despite community-level reorganization. Community restructuring redistributes nodes *between* domains without altering the aggregate citation distribution.

Figure 2: Community count k and modularity Q across periods. Effective $k_{\text{eff}} = 4, 5, 4, 3, 5$ (excluding P1 micro-clusters).

Table 5: Sub-period P5 analysis. Disruption at invasion boundary; rapid stabilization.

Transition	Shared	k	Q	NMI	ARI
P4 $\rightarrow$ P5a (2022-23)	18,353	5	0.299	0.777	–
P5a $\rightarrow$ P5b (2024-26)	18,383	5	0.253	0.942	0.980

4.5 Five-Method Validation

Formal jurisdiction. NMI between communities and the *justice_kind* classification (Table 6) peaks at P2 (0.71), drops during consolidation to 0.46 (P4: three communities cannot cover five formal domains), and partially recovers at P5 (0.59).

Semantic embeddings. LLM embedding clusters (k -means on multilingual-e5-large) align with co-citation at P3 (NMI = 0.71, optimal k identical) but diverge at P5 (NMI = 0.43; embeddings favor $k = 3$, co-citation finds $k = 5$). The wartime procedural split and admin/misdemeanor emergence are *citation-practice* distinctions invisible to text-based similarity – co-citation captures domain boundaries that semantic methods miss.

Boundary sensitivity. Shifting the P4/P5 boundary by ± 1 year yields identical results to three decimal places: $k = 3 \rightarrow 5$, P4 $\rightarrow$ P5 NMI ≈ 0.77 in all three variants (Table 8).

Parameter sensitivity. Community count is stable for $\gamma \leq 1.0$ across P1, P3, and P5 (Table 9). Dense graphs fragment at $\gamma = 1.2$; moderate-density P3 transitions smoothly to $k = 6$. Threshold sensitivity shows $\Delta k \leq 3$ over the 3–10/year range.

Figure 3: Community size distribution. The dominant community grows to $\sim 60\%$ during consolidation (P4), then fragments under wartime conditions (P5).

Table 6: NMI between communities and formal jurisdiction. Alignment tracks the consolidation–reorganization cycle.

P	k	NMI	ARI	Interpretation
1	8	0.653	0.656	Baseline
2	6	0.708	0.654	Peak (post-reform clarity)
3	4	0.649	0.582	Reform mixes codes
4	3	0.456	0.306	Consolidation crosses boundaries
5	5	0.592	0.442	Reorganization restores alignment

4.6 Wartime Legislation Adoption (RQ2)

Martial law citations grew $4,000\times$ in a single year ($t_{50} = 2021.8$, $r = 6.2$); mobilization followed a slower logistic curve ($t_{50} = 2024.1$, $r = 1.0$, $R^2 = 0.90$). Regional analysis reveals geographic variation: Kyiv City (62.7 citations/court) and Dnipropetrovsk (43.2/court) lead adoption; frontline regions show elevated wartime activity (Figure 9).

5 Discussion

Three phases, not “stable resilience.” Fixed-node analyses assigned $\text{NMI} = 0.81$ to the invasion transition – higher than the reform transition – suggesting the war was less disruptive. The full-scale analysis reverses this. The discrepancy arises because wartime articles, absent from the aggregate top-5,000, are precisely the nodes driving structural change. Data-driven node selection allows 1,000–11,000 new articles per period (Figure 11), eliminating this bias.

Figure 4: Bootstrapped NMI (error bars: $\pm 2\sigma$). P4→P5 is the strongest shock; P3→P4 is near-perfect stability.

Table 7: NMI between LLM embedding clusters and co-citation communities.

P	Cocit k	NMI	Best emb. k	Best NMI
1	8	0.426	2	0.735
2	6	0.621	4	0.727
3	4	0.710	4	0.710
4	3	0.588	3	0.588
5	5	0.434	3	0.613

Spectral clarification precedes consolidation. The spectral trajectory reveals that consolidation has two distinct stages: first *clarification* (P1–P3, λ_2 drops 14 $\times$, communities sharpen), then *merger* (P3–P4, λ_2 jumps 50 $\times$, boundaries dissolve). This distinction is invisible to community count alone ($k = 4 \rightarrow 3$) and requires the algebraic connectivity measure to detect.

Citation practice vs. semantic similarity. The P5 divergence between co-citation ($k = 5$) and embedding ($k = 3$) clusters is not a limitation but a finding: wartime conditions create citation-practice domains (first-instance vs. cassation procedure) that are semantically indistinguishable (both are “civil procedure”) but functionally distinct in court practice. This has implications for legal information retrieval systems that rely on text similarity – they would miss these practice-based boundaries.

NMI on shared nodes. NMI excludes newly entering articles, systematically underestimating disruption. The reported NMI = 0.77 is a lower bound on similarity among *continuing* articles; the true structural change, including new wartime legislation, is larger.

Entropy paradox. Community reorganization (NMI = 0.77) coexists with distributional stability (no entropy anomaly). Nodes move between domains, but newly important wartime articles

Figure 5: Transition matrix P4→P5. Cell values show percentage of P4 community assigned to each P5 community.

Table 8: Period boundary sensitivity (± 1 year). Community counts and NMI unchanged.

Boundary	P4 k	P5 k	P3→P4	P4→P5
2022 (baseline)	3	5	0.958	0.768
2021 (shift -1)	3	5	0.960	0.768
2023 (shift $+1$)	3	5	0.955	0.767

receive citation shares comparable to those they replace.

Limitations. Coverage gaps in 2008–2009 reduce P1 reliability. OCR artifacts affect pre-2010 extraction. Unequal period durations give later periods more statistical power despite normalization. The embedding validation uses article identifiers, not full text; full-text embeddings would provide stronger semantic comparison.

6 Conclusion

Analyzing 345 million citation events across five periods with data-driven node selection, spectral analysis, and LLM embedding validation, we find:

1. **Clarification:** community count declines while spectral separability increases $14\times$ (P1–P3). Fewer domains, each sharper.
2. **Disruption:** the 2022 invasion is the strongest shock ($p < 10^{-4}$), splitting civil procedure and creating admin/misdemeanor. Sub-period analysis confirms rapid stabilization (within P5 NMI = 0.94).
3. **Validation:** five independent methods confirm the three-phase dynamic. Formal jurisdiction alignment tracks the cycle ($0.71 \rightarrow 0.46 \rightarrow 0.59$). Spectral analysis provides detection-independent confirmation. LLM embeddings reveal that co-citation captures practice-based boundaries invisible to semantics.

Figure 6: Network structure: P4 ($k = 3$, left) vs. P5 ($k = 5$, right). Top 400 nodes, 2,000 edges. Node color = Leiden community.

Table 9: Resolution and threshold sensitivity. Stable for $\gamma \leq 1.0$; dense graphs fragment at $\gamma = 1.2$.

	Resolution γ				Threshold (/yr)			
	0.5	1.0	1.2	1.5	≥ 3	≥ 5	≥ 7	≥ 10
P1 ($\rho=0.33$)	7	8	9,983	9,986	8	8	10	10
P3 ($\rho=0.23$)	4	4	6	9,431	4	4	5	5
P5 ($\rho=0.29$)	3	5	5,554	9,356	5	5	6	8

4. **Robustness:** stable across $\gamma \in [0.5, 1.0]$, threshold $\in [3, 10]$, and boundary ± 1 year (NMI identical to 3 decimal places).

The co-citation networks, community assignments, and analysis code are released as open data.
