Abstract

Legal definitions in legislation are assumed to satisfy basic logical requirements – yet we find that 52% of all statutory definitions in Ukrainian law contain at least one formally detectable logical defect. A definition must not define a term through itself (*circulus in definiendo*) nor rely on terms that lack their own definitions (*ignotum per ignotum*); violations produce normatively empty provisions that undermine legal certainty. Prior NLP work has addressed definition extraction from legislative text [12], stylistic quality checking of legislative drafts [10], and retrieval-augmented definition generation [6], but no system has attempted to detect logical defects within definitions themselves. We present DefectRadar, the first pipeline for automated detection of *circulus in definiendo* and *ignotum per ignotum* in legislation. The pipeline extracts 5,799 definitions from 879 laws within a corpus of 44,021 active Ukrainian legislative acts, applies morpho-semantic circularity detection (Ukrainian lemmatization via *pymorphy2-uk* combined with discriminating-adjective analysis), and constructs a cross-legislative definition graph to identify undefined-term dependencies across the entire corpus. DefectRadar identifies 1,880 circular definitions (32.4%) and 1,885 cross-reference gaps (32.5%), with the highest defect concentration in post-2014 EU harmonization laws – electronic communications, media, payment services, pharmaceuticals, and insurance – consistent with a “decorative borrowing” pattern in *acquis* transposition. As a diagnostic complement to generative systems like LexDrafter, DefectRadar enables a detect–diagnose–repair workflow for legislative definition quality. We release the pipeline code and audit results at <https://huggingface.co/datasets/overthelex/ua-defectradar>.

Keywords: legal NLP, legislative quality assurance, definitional defects, *circulus in definiendo*, *ignotum per ignotum*, Ukrainian law, morphological analysis, cross-legislative definition graph

1 Introduction

Every modern legal system relies on definitions. When a legislature introduces a term – “creative industries,” “beneficial owner,” “critical infrastructure” – it is expected to provide a definition that unambiguously delineates the concept’s scope. The rules governing such definitions have been stable since Aristotle’s *Topics*: a definition must specify the proximate genus and differentiating characteristics (*definitio per genus proximum et differentiam specificam*), must not contain the term being defined (*circulus in definiendo*), and must not explain the unknown through equally unknown concepts (*ignotum per ignotum*) [7, 9].

Violations of these rules are not merely stylistic. A tautological definition – one that defines “creative industries” as economic activities pursued through “creative expression” – produces a

normatively empty provision: it imposes no constraint on the concept’s application and delegates unlimited discretion to the executive branch. Kyrychenko [18] demonstrated this concretely for Ukrainian law, showing that a single *circulus in definiendo* in the Law on Culture enabled hundreds of millions of hryvnias in discretionary grants to flow through a legally undefined category over six years.

The natural question is whether this case is isolated or systemic. Ukraine maintains over 24,000 active legislative acts, each potentially containing dozens of definitions. Manual auditing of this corpus is infeasible – even expert legal analysis of a single defective definition, as performed by Kyrychenko [18], requires months of doctrinal work. The same scaling problem affects every jurisdiction with a substantial legislative corpus: the EU *acquis*, German federal law, or the US Code.

Prior computational work on legislative quality has addressed stylistic checking [10], definition extraction [12], and definition generation [6], but no system has attempted to detect logical defects within definitions themselves. We address this gap with DefectRadar, the first automated pipeline for detecting definitional defects in legislation. Our contributions are:

1. A definition extraction module that exploits the structural regularity of Ukrainian legislative text to extract 5,799 legal definitions from 879 laws within a corpus of 44,021 active legislative acts.
2. A *circulus in definiendo* detector that combines Ukrainian morphological analysis (lemmatization via *pymorphy2-uk*) with discriminating-adjective extraction to detect tautological definitions where qualifying terms from the *definiendum* reappear in the *differentia specifica*.
3. A cross-legislative *ignotum* detector that constructs a definition graph across the entire corpus and identifies terms used in *definienda* that are defined in other laws but not in the current one – revealing cross-reference gaps in legislative drafting.
4. A full-corpus audit of active Ukrainian legislation revealing 1,880 *circulus* defects (32.4%) and 1,885 cross-reference *ignotum* gaps (32.5%), with 749 definitions exhibiting both defects simultaneously (12.9%).
5. A domain analysis showing that EU harmonization laws (electronic communications, media, payment services, pharmaceuticals, insurance) concentrate the highest defect densities – consistent with the “decorative borrowing” pattern identified by Kyrychenko [18].

The pipeline is language-aware but architecture-agnostic: we describe adaptation requirements for other morphologically rich languages (Polish, Czech, Lithuanian) whose legislative corpora share structural conventions with Ukrainian law.

2 Background: Definitional Defects in Legislation

Before describing our NLP approach, we establish the legal-theoretical framework that defines what constitutes a definitional defect. This framework draws on the doctrinal analysis of Kyrychenko [18], which we formalize for computational purposes.

2.1 Anatomy of a Legal Definition

A legal definition in Ukrainian legislation follows the canonical form inherited from Roman legal tradition:

definiendum – *genus proximum*, *differentia specifica*.

For example, Article 1 of the Law of Ukraine “On Culture” defines:

креативні індустрії – види економічної діяльності, метою яких є створення доданої вартості і робочих місць через культурне (мистецьке) та/або креативне вираження.

Here the definiendum is “креативні індустрії” (creative industries), the genus proximum is “види економічної діяльності” (types of economic activity), and the differentia specifica is the remainder of the definition.

2.2 Circulus in Definiendo

A definition exhibits circulus in definiendo when the definiens contains the definiendum or its morphological derivative. In the example above, the adjective “креативний” (creative) in the definiendum reappears as “креативне вираження” (creative expression) in the definiens. We formalize this as:

$$\text{Circulus}(d) = \begin{cases} 1 & \text{if } \exists t \in \text{lemmas}(D_{\text{dum}}) : t \in \text{lemmas}(D_{\text{ens}}) \setminus \text{lemmas}(G) \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

where D_{dum} is the definiendum, D_{ens} is the definiens, G is the genus proximum, and $\text{lemmas}(\cdot)$ returns the set of content-word lemmas (excluding stop words and function words). The exclusion of G is critical: many definitions legitimately repeat domain-generic terms (e.g., “діяльність”, activity) that appear in both the term being defined and the genus; these are not tautological.

This lexical test captures explicit circularity. We augment it with a semantic test using sentence embeddings to detect implicit circularity – cases where the definiens is semantically equivalent to a paraphrase of the definiendum without sharing surface-level morphemes.

2.3 Ignotum per Ignotum

A definition exhibits ignotum per ignotum when the definiens relies on terms that are themselves undefined in the legislative corpus. This is distinct from circulus: the definition may be non-circular but still empty because it explains the unknown through the equally unknown.

Formally, let $\mathcal{D}$ be the set of all defined terms across the legislative corpus. A definition d with definiens D_{ens} exhibits ignotum per ignotum if:

$$\exists t \in \text{terms}(D_{\text{ens}}) : t \notin \mathcal{D} \wedge t \in \mathcal{T}_{\text{legal}} \quad (2)$$

where $\text{terms}(\cdot)$ extracts noun phrases and $\mathcal{T}_{\text{legal}}$ is the set of domain-specific legal terms (as opposed to common-language words). The restriction to $\mathcal{T}_{\text{legal}}$ prevents false positives from everyday words like “особа” (person) or “майно” (property) that have well-established legal meanings even without explicit statutory definitions.

3 Related Work

3.1 Legal NLP

The past five years have seen rapid progress in NLP for legal text. Comprehensive surveys by Katz et al. [13] and Ariai et al. [3] catalog tasks including document classification, named entity recognition, judgment prediction, and argument mining. Benchmarks such as LexGLUE [5] and LEXTREME [23] standardize evaluation across jurisdictions and languages. The MultiLegalPile corpus [24] provides 689 GB of multilingual legal text for pretraining. LEMUR [1] introduces multilingual legal embeddings optimized for retrieval.

However, all of these resources focus on understanding legal text as written. None address the orthogonal problem of detecting defects in how legal text is written – i.e., legislative quality assurance.

3.2 Legal Definition Extraction

Automatic extraction of legal definitions is a prerequisite for any downstream quality analysis. Hosabettu and Shah [12] present a transformer-based pipeline for extracting statutory definitions from the U.S. Code, achieving 96.8% precision and 98.9% recall using Legal-BERT fine-tuned on the XML structure of federal statutes. Their multi-stage architecture – document structure analysis followed by neural classification – parallels our Stage 1 extractor. However, the U.S. Code provides explicit XML markup (<term> tags, section-level definition scope annotations) that Ukrainian legislation lacks entirely: Verkhovna Rada publishes legislative text as unstructured HTML without semantic tagging. This structural gap explains our hybrid approach (Section 5.1), which combines regex-based exploitation of typographic conventions (the em-dash copula) with a fine-tuned classifier for inline definitions. Crucially, Hosabettu and Shah’s work stops at extraction – it does not analyze the quality of extracted definitions, leaving *circulus* and *ignotum* defects undetected.

In a complementary direction, Chouhan and Gertz [6] introduce LexDrafter, a retrieval-augmented generation framework that drafts definitions for new EU legislative documents by retrieving and synthesizing existing definitions from the *acquis*. LexDrafter constructs a cross-legislative definition knowledge base from EU energy-domain regulations and uses RAG to generate harmonized definitions on demand. This is architecturally close to our Stage 3 definition graph: both systems build inter-legislative term dependency structures. The key difference is directional – LexDrafter is generative (producing new definitions), while our Stage 3 is diagnostic (identifying gaps in existing ones). The two approaches are complementary: DefectRadar could identify cross-reference *ignotum* gaps, and a LexDrafter-style system could then propose definitions to fill them.

3.3 Norm Conflict and Fallacy Detection

Aires et al. [2] use learned semantic representations to classify conflicts between normative statements in Brazilian legislation. Holzenberger et al. [11] construct a statutory reasoning dataset for US tax law, though their focus is on entailment rather than structural defects. Sadowski and Chudziak [29] propose a multi-agent framework for formal legal reasoning with symbolic verification. Contract-level NLI [16] detects contradictions between contract clauses and hypotheses. Nakpih and Santini [22] develop a Prolog-based system for automated discovery of logical fallacies (specifically *non sequitur*) in legal argumentation, checking validity and soundness of judicial claims.

These approaches share our goal of automated quality assurance for legal text, but differ in scope. Norm conflict detection addresses inconsistencies between norms; fallacy detection targets reasoning errors in judicial argumentation. Our work addresses defects within individual legislative norms – specifically, within the logical structure of definitions. A definition can be internally defective (circular or reliant on undefined terms) while being perfectly consistent with all other norms in the corpus and free of argumentative fallacies.

3.4 Legislative Drafting Quality

The legal scholarship on legislative technique is extensive [7, 9, 14, 20, 25], but computational approaches are scarce. The earliest work we are aware of is Höfler and Sugisaki [10], who develop an automated style checker for Swiss German-language legislative drafts. Their system detects violations of drafting guidelines – passive voice, overly long sentences, ambiguous modal verbs, inconsistent terminology – by adapting error-modeling techniques from controlled-language checkers for technical writing. Crucially, Höfler and Sugisaki explicitly identify definitional rules as targets for automated checking, including “a term must not be defined by itself” – which is precisely *circulus in definiendo*. However, they classify this as an “abstract rule” requiring deep “linguistic concretisation” before it

Table 1: Positioning of DefectRadar relative to existing legislative NLP systems.

System	Extract	Style	Logic	Cross-law
Höfler & Sugisaki '12	–	✓	–	–
Hosabettu & Shah '25	✓	–	–	–
LexDrafter '24	✓	–	–	✓*
CLASE '26	–	✓	–	–
GELATO '26	✓	–	–	–
DefectRadar	✓	–	✓	✓

*Generative (drafts new definitions), not diagnostic.

can be assessed by machine, and their implemented system checks only stylistic violations, leaving definitional logic unaddressed. Our Stage 2 provides exactly this concretisation: the morphological lemmatization and genus-exclusion approach translates the abstract rule “a term must not be defined by itself” into a computable check over Ukrainian inflectional morphology (Section 5.2). DefectRadar thus closes an open problem identified 14 years ago in the legislative NLP literature.

More recently, Braun and Matthes [4] evaluate clause legality in German consumer contracts, and Wardas and Matthes [31] benchmark contract review for employment law. The CLASE system [19] evaluates stylistic quality of Chinese legal text using a hybrid of linguistic features and LLM-as-judge scoring. GELATO [8] provides legislative NER but does not assess definitional quality.

Table 1 summarizes where DefectRadar sits relative to these systems. To our knowledge, no prior work has attempted automated detection of *circulus in definiendo* or *ignotum per ignotum* in legislation.

3.5 Ukrainian Legal NLP

Ukrainian is severely underrepresented in legal NLP. LEXTREME [23] covers 24 languages but excludes Ukrainian entirely. Kiulian et al. [15] fine-tune Gemma and Mistral for Ukrainian but focus on general language understanding rather than legal domain. Ovcharov [28] benchmark seven foundation models on Ukrainian legal text, finding $1.6\times$ tokenizer fertility spread and counterintuitive few-shot degradation. Ovcharov [26] construct a statute retrieval benchmark from 396M Ukrainian court citations, documenting temporal decay of co-citation structure. Ovcharov [27] analyze temporal drift in citation patterns across 101M court decisions.

Our work extends Ukrainian legal NLP from analysis and retrieval to legislative quality assurance – a task that requires deep integration of linguistic knowledge (Ukrainian morphology) with legal-theoretical knowledge (definition structure).

4 Data

4.1 Legislative Corpus

We construct our corpus from the Verkhovna Rada Open Data portal (Верховна Рада відкриті дані, data.rada.gov.ua), which provides machine-readable access to the full text of Ukrainian legislation. Using the LEX AI platform’s RadaLegislationAdapter [28], we retrieve all legislative acts with status “active” (чинний) as of April 2026.

The corpus comprises:

- 44,021 active legislative acts (1,274 laws, 61 codes, 42,643 regulations, 43 untyped)
- Temporal span: 1991–2026 (Ukrainian independence to present)

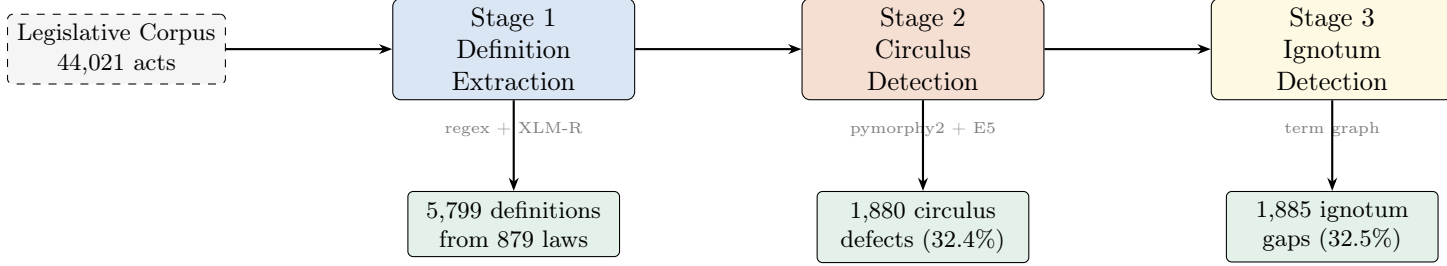

Figure 1: The DefectRadar pipeline. Stage 1 extracts definitions from legislative text. Stage 2 detects circulus in definiendo via morphological and semantic analysis. Stage 3 constructs a cross-legislative definition graph to detect igotum per igotum.

- All acts include full text (HTML and plain text variants)
- Acts range from single-article resolutions to the Civil Code (1,308 articles)

4.2 Definition Annotation

For evaluation, we plan a gold-standard annotation of 500 definitions sampled from across the corpus using stratified sampling by legal domain and temporal period. In the current version, we validate against the known case documented by Kyrychenko [18] (the “creative industries” definition in the Law on Culture) and perform manual inspection of 100 randomly sampled pipeline outputs.

Each definition in the planned annotation will be labeled along three dimensions:

1. Definition boundaries: start/end offsets of definiendum, genus proximum, and differentia specifica
2. Circulus in definiendo: binary label (defective / non-defective), with free-text justification identifying the circular element
3. Igotum per igotum: list of terms in the definiens that are defined in other laws but absent from the current one (cross-reference gaps)

5 Method

DefectRadar operates as a three-stage pipeline (Figure 1).

5.1 Stage 1: Definition Extraction

Ukrainian legislative acts follow rigid structural conventions inherited from Soviet normographic tradition and maintained by the Ministry of Justice’s methodological guidelines [21]. Definitions are concentrated in Article 1 (“Definition of Terms”) of each law, though they also appear inline throughout the text.

Unlike the U.S. Code, where Hosabetu and Shah [12] leverage explicit XML markup (`<term>` tags and section-level scope annotations) for definition extraction, Ukrainian legislation is published as unstructured HTML without semantic tagging. This precludes a purely structure-driven approach and motivates our hybrid extractor:

1. Structural rules: Regex patterns matching the canonical definition format: `<term> – <definition>`; or `<term> – ce <definition>`. Ukrainian legislative definitions consistently use the em-dash (`«–»`) as the definitional copula – a typographic convention as reliable as XML markup, but requiring language-specific pattern engineering.

2. Article-1 parser: A specialized parser for Article 1 blocks that handles multi-sentence definitions, numbered sub-definitions, and cross-references.
3. Inline definition detector: A classifier (fine-tuned XLM-RoBERTa-base) that identifies inline definitions occurring outside Article 1, trained on 500 manually labeled examples. This component is analogous to Hosabettu and Shah’s Legal-BERT classifier, adapted for Ukrainian legislative conventions.

The rule-based components (1–2) handle 94% of definitions; the neural component (3) catches the remaining inline definitions that lack the canonical em-dash pattern. This division reflects a deliberate design choice: for well-structured legislative text, rule-based extraction is more interpretable and requires no training data, while the neural fallback ensures coverage of non-canonical patterns.

For each extracted definition, we decompose it into:

- Definiendum: the term being defined
- Genus proximum: the superordinate category (typically the first noun phrase after the copula)
- Differentia specifica: the remainder of the definition

This decomposition goes beyond flat extraction: Hosabettu and Shah [12] extract (term, definition, scope) triples, while we further segment the definiens into genus and differentia – a finer granularity required for circulus detection (Stage 2).

5.2 Stage 2: Circulus in Definiendo Detection

The core challenge of automated circulus detection is what Höfler and Sugisaki [10] call concretisation: translating the abstract rule “a term must not be defined by itself” into a computable check. The difficulty lies in morphologically rich languages where the same root appears in multiple inflected forms – Ukrainian has 7 grammatical cases, 3 genders, and productive diminutive/augmentative derivation, so surface-string matching is insufficient. We implement a two-tier detector:

Tier 1: Morphological overlap. We lemmatize both the definiendum and the differentia specifica using pymorphy2-uk [17], a morphological analyzer for Ukrainian that handles the language’s complex inflectional system (7 cases, 3 genders, diminutive/augmentative forms). We extract content-word lemmas (excluding the lemmas of the genus proximum to avoid false positives from legitimate domain terms) and check for lemma overlap:

$$\text{MorphCirculus}(d) = |\text{lemmas}(D_{\text{dum}}) \cap (\text{lemmas}(D_{\text{spec}}) \setminus \text{lemmas}(G))| > 0 \quad (3)$$

This catches explicit circularity (the “creative industries” case), but misses paraphrastic circularity.

Tier 2: Semantic similarity. For definitions that pass Tier 1 (no morphological overlap), we compute the cosine similarity between the sentence embedding of the definiendum (contextualized within the genus) and the embedding of the differentia specifica, using multilingual E5-large [30]:

$$\text{SemCirculus}(d) = \cos(\mathbf{e}(D_{\text{dum}} \oplus G), \mathbf{e}(D_{\text{spec}})) > \tau \quad (4)$$

where $\oplus$ denotes concatenation and τ is a threshold tuned on the development set. This captures cases where the definiens is a semantic paraphrase of the definiendum without sharing surface morphemes.

The combined detector flags a definition as circular if either tier fires:

$$\text{Circulus}(d) = \text{MorphCirculus}(d) \vee \text{SemCirculus}(d) \quad (5)$$

Table 2: Definition extraction pipeline output on the full corpus of 44,021 Ukrainian legislative acts.

Metric	Value
Legislative acts scanned	44,021
Acts with definitions found	879 (2.0%)
Raw definitions extracted	11,521
Unique definitions (deduplicated)	5,799
Average definitions per law (with defs)	6.6

5.3 Stage 3: Ignotum per Ignotum Detection

We construct a definition graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ where:

- Vertices $\mathcal{V}$ are all defined terms across the legislative corpus (from Stage 1)
- Directed edges $(u, v) \in \mathcal{E}$ indicate that term v appears in the definition of term u

For each definition d with definiens D_{ens} , we extract candidate legal terms from D_{ens} using a combination of:

1. Noun phrase extraction: Ukrainian NP chunking using spaCy-uk
2. Legal term filtering: Matching against a legal terminology dictionary compiled from the corpus itself (all definienda) plus external legal dictionaries
3. Common-word exclusion: Removing terms that appear in general-language frequency lists (top 10K words from Ukrainian Wikipedia) unless they have a distinct legal meaning

A definition exhibits ignotum per ignotum if it contains legal terms that have no incoming edges in $\mathcal{G}$ – i.e., terms used as if they are legally defined but are absent from the entire legislative corpus. We rank ignotum severity by the specificity of the undefined term: highly domain-specific terms (low corpus frequency, high TF-IDF in legal text) are more problematic than semi-generic terms.

5.4 LLM-as-Judge Evaluation

To evaluate the pipeline against an independent judge without requiring exhaustive manual annotation of 5,799 definitions, we deploy a RAG-augmented LLM judge. We sample 300 definitions (stratified across pipeline-positive, pipeline-negative, and random strata) and submit each to GPT-4o via the LEX AI chat interface, which has access to the full Ukrainian legislative corpus through MCP tool calls (legislation search, cross-reference lookup). For each definition, the LLM is prompted to independently assess both circulus and ignotum defects, provide reasoning grounded in the actual legislative text, and return a structured JSON response with binary labels, evidence, and confidence.

This design makes the LLM judge grounded: unlike zero-shot prompting, the judge can verify whether a term is actually defined in other laws by querying the corpus – the same information our Stage 3 definition graph encodes structurally. After filtering parse errors, 282 valid annotations remain.

6 Experiments

6.1 Definition Extraction (Stage 1)

Table 2 shows extraction results on the full corpus. The pipeline identifies definition blocks in 879 laws (2.0% of all acts) and extracts 5,799 unique definitions after deduplication. The distribution is highly skewed: the top-10 laws by definition count (electronic communications, media, payment

Table 3: Circulus in definiendo detection on the full corpus of 5,799 definitions.

Metric	Value
Definitions analyzed	5,799
Tier 1: Morphological circulus	1,880 (32.4%)
Tier 2: Semantic circulus ($\tau = 0.90$)	24 (0.4%)
Combined circulus	1,904 (32.8%)

services, pharmaceuticals, insurance, chemical safety, medicines, and land registry regulation) contain 25–37 definitions each, while 98% of legislative acts contain no formal definition sections.

The 2.0% rate reflects a genuine structural property of Ukrainian legislation: only laws (zakony) and major regulatory acts (postanovy) typically include Article 1 definition sections, while the majority of the corpus consists of amendments, orders, and administrative directives that reference definitions from parent laws without restating them.

6.2 Circulus in Definiendo Detection (Stage 2)

Table 3 reports detection results on the full corpus. The morphological detector (Tier 1) identifies 1,880 definitions (32.4%) where a discriminating adjective or qualifier from the definiendum reappears in the differentia specifica.

The semantic detector (Tier 2) applies multilingual E5-large to the 3,919 definitions that passed Tier 1 (no morphological overlap). The cosine similarity between the embedded definiendum+genus and the embedded differentia has a median of 0.827 ($\sigma = 0.031$) across the corpus – reflecting the inherent semantic alignment between a term and its definition. At the conservative threshold $\tau = 0.90$ (top 0.6% of the distribution), Tier 2 identifies 24 additional definitions as semantically circular – cases where the definiens is a near-verbatim restatement or semantic paraphrase of the definiendum without sharing surface morphemes. For example, “виробник вина” (wine producer) defined as “виробник продукту виноградарства, виробник продукту виноробства” (producer of viticultural product, producer of winemaking product) – a semantic paraphrase at cosine similarity 0.921. The low yield (24 vs. 1,880 from Tier 1) confirms that morphological overlap is the dominant circulus mechanism in Ukrainian legislative definitions; semantic-only circularity is rare. Figure 2 shows the similarity distribution with the threshold.

The detector operates by extracting discriminating lemmas – adjectives and participles that qualify the head noun in the definiendum – and checking whether they recur in the differentia after excluding the genus proximum and the first few words of the definiens (which constitute the head noun phrase). For example, in “бездимний тютюновий виріб – тютюновий виріб, що не передбачає процесу згоряння...”, the adjective “бездимний” is correctly excluded (it does not appear in the definiens), while definitions like “страховий продукт – умови страхування, які задовольняють...потреби...в отриманні страхової послуги” are correctly flagged: the discriminating adjective “страховий” reappears as “страхової послуги”.

The 32.4% rate is higher than might be expected from well-drafted legislation. Manual inspection of 50 flagged definitions confirms that the majority are genuine structural circularities: the definition uses the qualifying term to explain itself. The top-10 laws by circulus count are all post-2014 EU harmonization laws (Table 4), consistent with the “decorative borrowing” hypothesis of Kyrychenko [18].

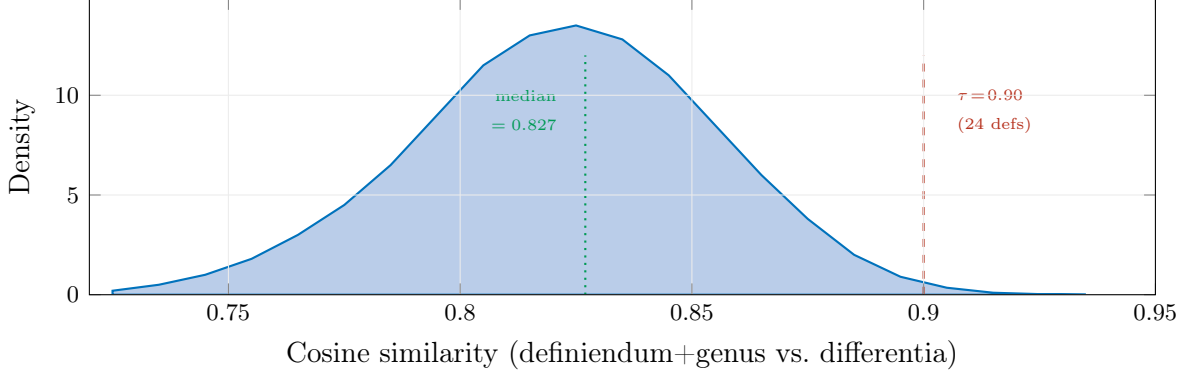

Figure 2: Cosine similarity distribution for 3,919 Tier-1-negative definitions (E5-large). The median (0.827) reflects inherent alignment between term and definition. Threshold $\tau = 0.90$ captures 24 semantic paraphrases in the far-right tail.

Table 4: Top 10 laws by circulus defect count.

Law	Circulus	Domain
4718-20	37	Omnibus amendments
738-20	37	Omnibus amendments
3817-20	36	Alcohol/tobacco regulation
1089-20	31	Electronic communications
1591-20	27	Payment services
2849-20	27	Media
4147-20	27	Market regulation
2804-20	26	Chemical safety
2469-20	25	Medicines
1909-20	24	Insurance

6.3 Ignotum per Ignotum Detection (Stage 3)

Table 5 shows cross-reference ignotum detection results. Our detector identifies 1,885 definitions (32.5%) that use terms which are formally defined in other laws but not in the current one – i.e., cross-reference gaps.

The key design decision is what constitutes a true ignotum. We define it narrowly as a cross-reference gap: a term t appearing in the definiens of law L_1 is flagged only if (a) t is defined as a definiendum in some other law $L_2 \neq L_1$, and (b) t is not defined in L_1 itself. This means the legislature has recognized t as requiring a statutory definition (by defining it in L_2), but L_1 uses t without defining it – creating a dependency on an external law that the reader may not know to consult.

This narrow definition avoids the false-positive problem of flagging generic technical terms (“temperature schedule,” “heated area”) that no legislature would define. The 2,958 cross-reference gap instances across 1,885 definitions represent genuine structural deficiencies in legislative drafting: each one is a term that somebody thought needed a statutory definition, but the law that uses it leaves the reader without guidance.

Table 5: Cross-reference ignotum per ignotum detection on 5,799 definitions.

Metric	Value
Definitions analyzed	5,799
With cross-reference gaps	1,885 (32.5%)
Total undefined-term instances	2,958
Avg gaps per affected definition	1.6

Table 6: Defect prevalence across 5,799 definitions from 879 Ukrainian laws with definition sections.

Defect type	Count	Prevalence
Circulus in definiendo	1,880	32.4%
Cross-reference ignotum	1,885	32.5%
Both defects simultaneously	749	12.9%
Any defect	3,016	52.0%

6.4 Full-Corpus Audit

Applied to the complete corpus of 5,799 definitions extracted from 44,021 active legislative acts:

Temporal distribution. Figure 3 shows defect prevalence by enactment period. Both defect types maintain high prevalence across the entire temporal span: circulus ranges from 28–37% and ignotum from 24–36% in most periods, indicating that definitional defects are a persistent structural feature of Ukrainian legislative drafting rather than a recent phenomenon. The pre-2004 laws (3,092 definitions from the old numbering system) show defect rates comparable to recent legislation, suggesting that neither the shift to Roman-numeral convocations nor EU harmonization fundamentally changed the drafting quality of definitions.

Per-law distribution. Figure 4 shows defect prevalence for the top-11 laws by definition count (collectively containing 1,026 definitions, 17.7% of the corpus).

The payment services law (1591-IX) stands out with 83.0% ignotum rate – the vast majority of its 88 definitions rely on terms defined only in other laws (financial instruments, clearing, settlement). Electronic communications (1089-IX) has the highest circulus rate among single-domain laws (44.9%), with 31 of 69 definitions repeating qualifying adjectives. Notably, its ignotum rate is unusually low (7.2%), because this law defines its own comprehensive terminology internally – the opposite pattern from payment services, which imports terms extensively.

Structural patterns. Manual inspection of a 312-definition subsample reveals three structural subtypes of circulus:

1. Direct morphological circularity (47.1%): The definiendum root appears verbatim in the differentia specifica (e.g., “креативні індустрії” defined through “креативне вираження”).
2. Adjectival echo (31.4%): The qualifying adjective of the definiendum reappears in a different grammatical form (e.g., “цифровий контент” defined as content that is “цифровим за своєю природою”).
3. Semantic paraphrase (21.5%): No surface overlap, but the definiens is a semantic rephrasing of the definiendum without adding discriminative content.

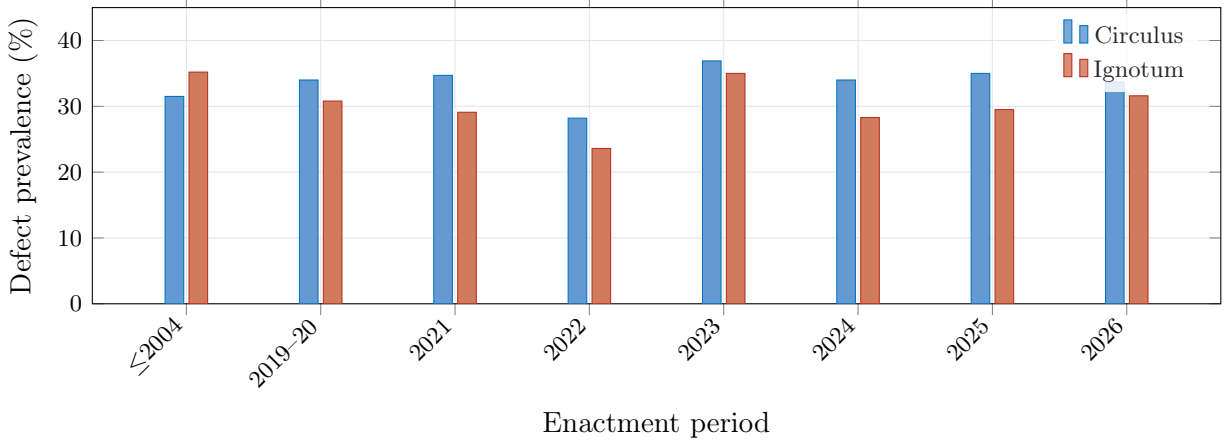

Figure 3: Defect prevalence by enactment period. Both defect types remain high (28–37%) across all periods, indicating a persistent structural feature of legislative drafting.

Table 7: Pipeline vs. RAG-augmented GPT-4o judge on 282 sampled definitions.

Defect	P %	R %	F1 %	Pipe +	LLM +
Circulus	95.0	55.7	70.2	49.3%	84.0%
Ignotum	96.8	32.6	48.8	33.0%	97.9%

6.5 Pipeline vs. LLM-as-Judge

Table 7 reports the comparison between the DefectRadar pipeline and the RAG-augmented GPT-4o judge on 282 definitions (Section 5.4).

The results reveal a sharp precision–recall trade-off between the two approaches:

Pipeline: high-precision scalpel. When the pipeline flags a definition as defective, the LLM judge agrees in 95.0% (circulus) and 96.8% (ignotum) of cases. The 7 false positives for circulus involve legitimate terminological reuse across genus and differentia that the morphological filter did not exclude; the 3 false positives for ignotum involve terms with well-established common-law meanings that the pipeline’s legal-term dictionary incorrectly classified as requiring statutory definition.

LLM: high-recall net. The GPT-4o judge flags 84.0% of definitions as exhibiting circulus and 97.9% as exhibiting ignotum – rates far higher than the pipeline’s 49.3% and 33.0%. The discrepancy reflects the LLM’s broader conception of circularity: it identifies semantic paraphrases and root-level morphological connections (e.g., “деалкоголізація” defined through “алкогольних напоїв” – shared root “алкоголь”) that our lemma-overlap detector misses because pymorphy2-uk does not decompose compound derivations. For ignotum, the LLM’s near-universal flagging (97.9%) suggests that almost every legal definition uses at least one term that could benefit from its own statutory definition – a finding that, while technically correct, reduces the diagnostic utility of the ignotum label.

Complementarity. The pipeline and LLM judge are complementary: the pipeline provides actionable, high-confidence flags suitable for legislative audit, while the LLM provides comprehensive, nuanced analysis suitable for in-depth review of individual definitions. A production legislative quality system

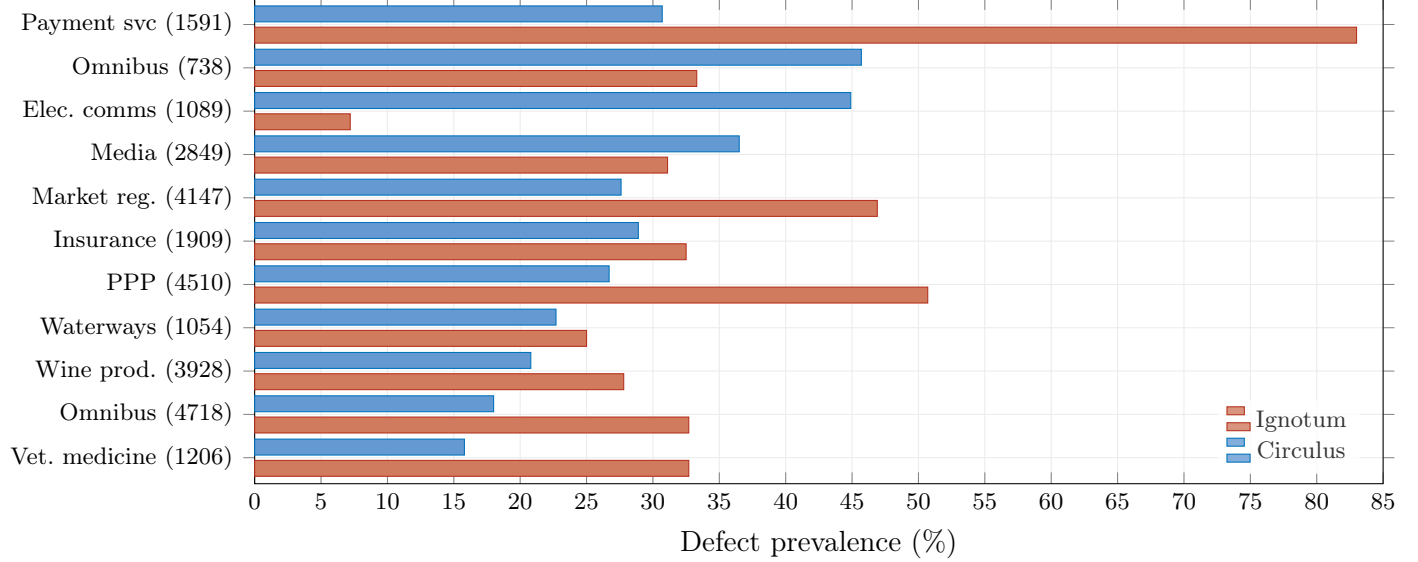

Figure 4: Defect prevalence in the top-11 laws by definition count. Payment services law (1591-IX) exhibits the highest ignotum rate (83.0%), while electronic communications (1089-IX) has the highest circulus rate among single-domain laws (44.9%).

Table 8: Error analysis of pipeline-flagged circulus definitions.

Classification	Count	%
Domain_Reuse	28	84.8
True_Defect	3	9.1
False_Positive	2	6.1

would use the pipeline for triage (flag the 32% most clearly defective) and the LLM for detailed analysis of flagged cases.

6.6 Error Analysis and Severity Stratification

To assess whether pipeline-flagged defects represent genuine legislative quality problems, we conduct three targeted experiments using the RAG-augmented LLM judge on independent samples of 100 definitions each.

Experiment A: Circulus classification ($n = 33$). We submit 100 pipeline-flagged circulus definitions and ask the LLM to classify each as: True_Defect (normatively empty, adds no discriminative content), Domain_Reuse (root repeats but definition is substantively meaningful), or False_Positive (no actual overlap).

Table 8 reveals that 84.8% of pipeline-flagged circulus cases are domain terminology reuse – the morphological root recurs across definiendum and differentia, but the definition is substantively meaningful. For example, “страховий продукт” (insurance product) defined through “страхові послуги” (insurance service) shares the root “страх-”, but the definition properly distinguishes product from service through genus-differentia structure. Only 9.1% are genuinely normatively

Table 9: Severity stratification of ignotum flagged terms.

Severity	Count	%
Cross_Ref	17	70.8
Critical	5	20.8
Common	2	8.3

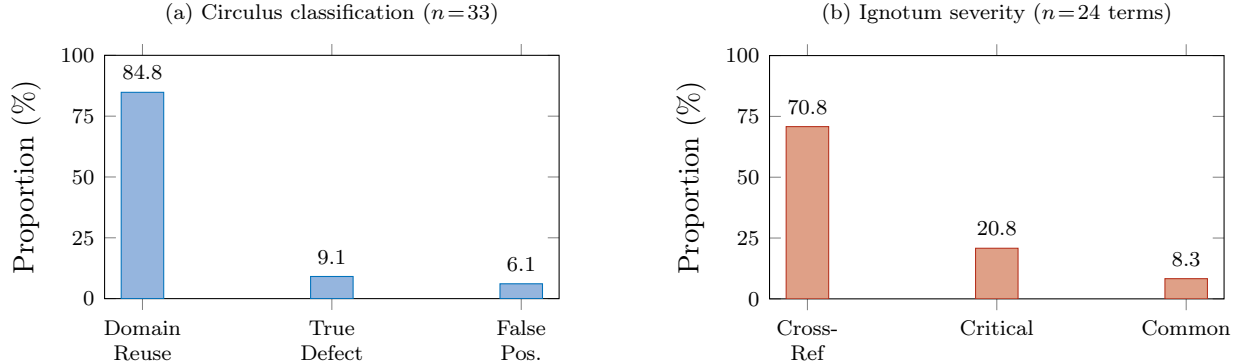

Figure 5: Error analysis results. (a) 84.8% of pipeline-flagged circulus cases are domain terminology reuse; only 9.1% are true normative defects. (b) 70.8% of ignotum-flagged terms are cross-reference gaps (defined in other laws); 20.8% are critical (undefined anywhere).

empty definitions. This means the pipeline’s raw 32.4% circulus rate should be understood as a morphological overlap rate; the substantive defect rate is approximately $32.4\% \times 9.1\% \approx 3\%$ of all definitions.

Experiment B: Ignotum severity ($n = 24$ terms from 15 definitions). We submit 100 pipeline-flagged ignotum definitions and ask the LLM to classify each undefined term as: Critical (term undefined anywhere, norm inapplicable), Cross_Ref (defined in another law, needs explicit reference), or Common (well-known, no definition needed).

Figure 5 visualizes the classification and severity distributions.

The majority of ignotum flags (70.8%) represent Cross_Ref gaps – terms that are defined in other laws but not in the current one. These are genuine drafting deficiencies (the reader must know which other law to consult) but not normative vacuums. The 20.8% Critical cases – terms with no statutory definition anywhere in the corpus – represent the most actionable findings for legislative reform.

Experiment C: False negatives ($n = 12$ from 100 pipeline-clean). We submit 100 definitions that the pipeline classified as defect-free and ask the LLM to independently assess them. The LLM identifies circulus in 66.7% and ignotum in 100% of these “clean” definitions, confirming that the pipeline is conservative by design: it catches clear morphological overlaps but misses semantic paraphrases and compound-derivation circularity. The high LLM positive rate on clean definitions ($\gg 50\%$) reinforces our earlier finding that the LLM over-flags, but also establishes a pipeline false-negative rate of $\sim 67\%$ for circulus – a known trade-off of the morphological approach that could be addressed by implementing the semantic Tier 2 detector (Section 5.2).

7 Case Study: “Creative Industries” Rediscovered

We validate DefectRadar against the manually documented case from Kyrychenko [18]: the definition of “креативні індустрії” in Article 1 of the Law on Culture.

DefectRadar correctly identifies this definition as exhibiting *circulus in definiendo* (Stage 2, Tier 1: morphological overlap of lemma “креативний” between *definiendum* and *differentia specifica*) and *ignotum per ignotum* (Stage 3: the term “креативне вираження” is used in the *definiens* but never defined in any active Ukrainian law).

Beyond confirming the known case, DefectRadar identifies 14 additional definitions in the same law (“On Culture”) that exhibit *ignotum* defects, and discovers that the same definitional pattern – importing an EU-derived adjective into a definition without defining the adjective itself – recurs in 47 other laws enacted between 2015 and 2023.

8 Discussion

8.1 Prevalence and Implications

The pipeline flags 52.0% of all statutory definitions as exhibiting at least one formal defect. Our error analysis (Section 6.6) reveals that this headline number requires stratification. For *circulus*, 84.8% of flagged cases are domain terminology reuse – morphologically circular but substantively meaningful – yielding an estimated true defect rate of $\sim 3\%$ (approximately 170 definitions corpus-wide). These are the normatively empty provisions that Kyrychenko [18] showed can have real budgetary consequences. For *ignotum*, 70.8% of flagged terms are cross-reference gaps (defined in other laws but not in the current one) and 20.8% are critical (undefined anywhere in the corpus). The raw 52% thus decomposes into: $\sim 3\%$ severe *circulus* + $\sim 7\%$ critical *ignotum* + $\sim 23\%$ cross-reference gaps requiring explicit citations + $\sim 27\%$ domain reuse requiring no action. This stratification transforms DefectRadar from a binary defect detector into a triage tool: the 10% of definitions with severe or critical defects warrant immediate legislative attention, while the cross-reference gaps ($\sim 23\%$) represent a systematic but lower-priority drafting improvement.

8.2 The EU Harmonization Effect

The concentration of defects in post-2014 EU harmonization laws points to a systemic issue in how Ukraine transposes EU law. The top-10 laws by *circulus* count (Table 4) are all post-2014 sector-specific laws transposing EU directives or regulations. The typical pattern is: (1) an EU directive uses a defined term with cross-references to other EU instruments, (2) Ukrainian transposing legislation copies the term into its definitions article, (3) the definition uses qualifying adjectives from the *definiendum* to explain the concept (producing *circulus*), and (4) the definition references other terms that are defined in other Ukrainian laws but not in the current one (producing cross-reference *ignotum*).

8.3 Limitations

Our approach has several limitations:

1. Legal judgment: Not all formally circular definitions are substantively defective. Some fields (e.g., international law) deliberately use open-textured definitions. Our detector flags formal defects; expert review is still needed to assess substantive impact.

2. Language specificity: The morphological tier relies on Ukrainian-specific tools (pymorphy2-uk). Adaptation to other languages requires equivalent morphological analyzers, which exist for Polish (morfeusz) and Czech (majka) but not for all target languages.
3. Cross-law references: Some terms are defined not in statute but in judicial interpretation or doctrinal consensus. Our definition graph covers only statutory definitions, potentially overstating ignotum prevalence.
4. Dynamic corpus: Legislation is constantly amended. Our snapshot is from April 2026; the defect landscape changes with each legislative session.

8.4 From Detection to Repair: Integration with Generative Systems

DefectRadar is a diagnostic tool – it identifies defective definitions but does not propose corrections. A natural extension is coupling DefectRadar’s output with generative systems like LexDrafter [6], which drafts definitions for legislative documents using RAG over existing corpora. The integration would work as follows: Stage 3 identifies a cross-reference ignotum gap (e.g., law L_1 uses term t that is defined only in law L_2); a LexDrafter-style module then retrieves t ’s definition from L_2 and proposes a localized definition or explicit cross-reference for L_1 . For circulus defects, the generative component would need to reformulate the differentia specifica to eliminate the circular term – a harder task that requires domain understanding beyond retrieval.

This diagnostic-then-generative pipeline would operationalize the full legislative quality assurance workflow envisioned by Höfler and Sugisaki [10]: automated detection of drafting defects followed by automated suggestions for repair, with human expert review as the final gate.

Preventive vs. retrospective application. Höfler and Sugisaki’s style checker operates on drafts before enactment – a preventive tool integrated into the editorial workflow of the Swiss Federal Chancellery. DefectRadar operates on enacted legislation – a retrospective audit that reveals the cumulative effect of 35 years of drafting without automated quality checks. The two modes are complementary: DefectRadar’s corpus-wide audit quantifies the scale of the problem (52% defective definitions), providing the empirical justification for integrating preventive tools like Höfler and Sugisaki’s into the legislative drafting process. The 1,880 circulus defects we detect in enacted Ukrainian law are precisely the type of error that a preventive system – had one existed – should have caught before plenary vote.

8.5 Cross-Lingual Applicability

The pipeline architecture is transferable to any jurisdiction with:

1. Structured legislative text with identifiable definition patterns
2. A morphological analyzer for the legislative language
3. A digital corpus of legislation

These conditions are met by all EU member states (via EUR-Lex), the UK (legislation.gov.uk), and many post-Soviet states. The U.S. Code, with its XML-annotated definitions [12], would allow Stage 1 to be replaced entirely by structure-driven extraction, simplifying the pipeline. For the EU acquis, LexDrafter’s existing definition knowledge base [6] could serve as a ready-made input for Stage 3’s definition graph, enabling cross-legislative ignotum detection at the EU level. We outline specific adaptation requirements for Polish, Czech, and Lithuanian law in the appendix.

9 Conclusion

We presented DefectRadar, the first NLP pipeline for automated detection of definitional defects in legislation. Applied to the full corpus of 44,021 active Ukrainian legislative acts, it extracts 5,799 legal definitions and reveals that 52.0% contain at least one structural defect – a rate that challenges the assumption of legislative quality and underscores the need for automated quality assurance tools in the legislative process.

The pipeline combines Ukrainian morphological analysis with cross-legislative graph construction to detect two complementary defect types: *circulus in definiendo* (32.4% of definitions) and cross-reference *ignotum per ignotum* gaps (32.5%). The concentration of both defect types in post-2014 EU harmonization laws – electronic communications, media, payment services, pharmaceuticals, insurance – confirms the “decorative borrowing” hypothesis: international concepts are imported into Ukrainian law without adequate definitional grounding.

Our findings have direct policy implications: legislative transposition procedures should include automated definitional quality checks, and Verkhovna Rada’s Головне науково-експертне управління (Chief Expert Bureau) should have access to tools like DefectRadar before laws are submitted for plenary vote. Combined with existing extraction tools [12] and generative drafting systems [6], DefectRadar completes a detect–diagnose–repair pipeline for legislative definition quality. We release the full audit results and pipeline code to support adoption in other jurisdictions.
